Virial Theorem #1 github.com/evanocathain/ Evan O Cathain Virial - Theorem The Virial Theorem applies to any stable system of particles bound by conservative forces partiles, Huid alements sturs in a galaxy TxE=0 ⇒ E=-PV, e.g. grovity galaries in a cluster ... Mydrostatic Equilibrium General Form: ct. Ewer Equations $9\overline{Du} = -\overline{\Delta}b - \overline{\partial}\overline{D} + (\overline{D} \times \overline{B})$ Novier-Stokes Equations $\frac{3\pi}{9\pi} + \beta(\overline{n}\cdot\overline{L})\pi$ [Ethis equation] . I dV get the general Virial Theorem 1 - 2T = 2U + SZ + MB total total total total thermal grav. Citarnal Sinding energy energy magnetic kindra bressine energy This is the general form of the Virial Theorem. Different simplified versions of this hold in different scenarios. In a star = will shortly derive this from egns of stellar structure =) in a frame where the star is not moving ar rotating =) LHS = 0 7 magnetic fields are regligible => MB = 0 =) 20 + 12 = 0 In a galaxy (cluster) =) stable orbito =) $\vec{I} = 0$, magnetic fields $\leq \mu G \Rightarrow M_B \Rightarrow 0$ density of gas very small $\Rightarrow U = 0$ =) $2T + \Omega = 0$ In a molecular class =) conditions such that $\ddot{I} \approx U \approx 0$ => 2T + 12 + MB = 0 =) if - I > 2T + MB = cland chlapses If Moint > MJeans star formation happens. Maynetic fields slow the allapse 7 set the scale for stars to be ~ 0.1 M.O. Without them would be ~ few M24 7 no H burning.

Virial Theorem #2 Evan O Catháin NB T, U terms are often conflated, perhaps because thermal energy is itself also a T= kinetic energy = $\int dm y^2$ the relatively the particle? $V = \text{thermal energy} = \int u \, dV = \frac{3}{2} \int nk \, T \, dV$ Lideal gas]

Lideal gas]

Lideal gas]

Lideal gas] In a star the derivation of the Virial Theorem goes as follows $\frac{(1)}{2} \times 4\pi r^{3} \Rightarrow 4\pi r^{3} \frac{dr}{dr} \frac{dr}{dn} = -\frac{GS(r)m(r)}{r^{2}} \frac{4\pi r^{2}S(r)}{4\pi r^{2}S(r)}$ \Rightarrow $4\pi r^3 dP = -\frac{Gm(r)dm}{}$ $\Rightarrow 3 \int_{1}^{1} V dP = - \int_{1}^{1} \frac{G_{m}(r) dm}{r}$ => 3 ([VP] cute - Surface PdV) = 12 => 3 SPW + I = 0 $P = P_{gas} + P_{rad}$ $= nkT + \frac{9}{3}T^4$ if gas prosure dominates, often the case for many MS stars, e.g. he Sun \Rightarrow 2U + $\Omega = 0$ What can we lear from this! Example 1: Could the sun be powered by gravitational contraction or cooling? $\Omega = -\int_{0}^{\infty} \frac{G m(r) dm}{r}$ Assume $\beta(r) = \beta_0 = constant$ $\Rightarrow \Omega = -\frac{3}{5} \frac{GM}{R}$ For the Sun => 12 = 2 x 10 "J $L_{\odot} = \frac{E}{time}$ = if powered by contraction = Age of Sun $\approx \frac{2 \times 10^{41} \text{ J}}{4 \times 10^{26} \text{ J/s}} \approx 20 \text{ Myr}$ 12 = -2U = if parered by cooling = Age of Sun 210 Myr

Virial Theorem #3 Evan 6 Catháin

Age of Sun => when this age was first calculated using the Virial Theorem it was already known to be < age of the Earth and so it was dear that another power source was in autim, which theres out to be nuclear burning.

Example 2: How hot are stors?

$$3\int PdV = -\Omega$$

$$P = nkT = kT\frac{g}{\langle m \rangle}$$
 $7 dm = gdV \Rightarrow \frac{3k}{\langle m \rangle} \int Tdm = \int \frac{G_m(r)dm}{r}$

For a star with radius R_n , integral over r from O to R_s Inside star $r < R_s \Rightarrow \frac{1}{r} > \frac{1}{R_s}$

$$\Rightarrow \frac{3k}{\langle m \rangle} \int T dm > \frac{\zeta}{Rs} \int_{0}^{\infty} m dm$$

$$\Rightarrow \frac{3k}{m} \langle T \rangle M_{W} > \frac{M_{W}^{2}}{R_{s}} \Rightarrow \langle T \rangle > \frac{G \langle m \rangle M_{W}}{6kR_{s}}$$

Sun mostly made of H, m = 1.67x10-27kg => <T > 3x106K

Example 3: How does the Virial Theorem indicate the existence of dark matter?

From spectral line observations can obtain velocities from Dypeler shift values \Rightarrow gives 1-D velocities $\sigma = v_{1D}$. But for spherical symmetry we have $v_{3D}^2 = 3\sigma^2$

$$\Rightarrow 2T = m_{ij} 3\sigma^{2} \text{ for each particle of mass } m_{i0}$$

$$\Rightarrow m_{i0} (3\sigma^{2}) = \frac{3}{5} \frac{GMm_{i0}}{R}$$
Assuming uniform density for simplicity

$$\Rightarrow M = \frac{5e^2R}{C}$$

For MW, $\sigma \approx 100 \text{km/s}$, $R \approx 100 \text{kpc}$ => $M_{100} \approx 10^{12} \text{M}_{\odot}$ But stellar mass, based on light enitted (recall L $\propto M^{-3.5}$ on Main Segurace) is Mstellar $\approx 10^{11} \text{M}_{\odot}$ => Dark Matter
